Abstract

Obesity is one of the main causes of inflammation. Previous studies have reported inconclusive results regarding the effect of bariatric surgery on inflammatory markers. This systematic review and meta-analysis is aimed at describing the effect of bariatric surgery on C-reactive protein (CRP), interleukin-6 (IL-6), tumor necrosis factor- α (TNF- α). PubMed/Medline and Scopus were systematically searched for all eligible studies from inception to June 2018. Results are expressed as weighted mean difference (MD) with 95% confidence intervals (CI) using a random effects model. Overall, 116 studies which evaluated serum CRP, IL-6, and TNF- α after bariatric surgery were included. Pooled effect size showed significant reduction in serum CRP (-5.30 mg/l, 95% CI -5.46, -5.15, P < 0.001), IL-6 (-0.58 pg/ml, 95% CI -0.64, -0.53, P < 0.001), and TNF- α (-0.20 pg/ml, 95% CI -0.39, -0.02, P = 0.031) with significant heterogeneity across studies (>95% for all factors). Bariatric surgery significantly lowered inflammatory factors; however, baseline BMI, follow-up duration and type of surgery could impact the extent of observed effects.

Keywords Bariatric surgery \cdot C-reactive protein \cdot Interleukin 6 \cdot Tumor necrosis factor- α \cdot Meta-analysis

Introduction

Nowadays, it is not obscure to anyone that obesity has become a major problem in both developed and developing countries [1]. Not only it could lead to major chronic diseases like cancer and CVD [2] but also it has a negative effect on individuals' self-esteem which could lead to severe depression [3]. The

detrimental effect of obesity on mental and physical performance lead to make people, even slightly overweight ones, to consider losing weight. Since the traditional recommendations such as following a strict diet or a hardcore exercise program have failed to be completely effective [4], people have been looking for a new easier way to get rid of all the fat mass.

Bariatric surgery is one of the new methods that has recently come to spotlight since it has been proven successful in losing weight [5]. Moreover, long-term studies proved it useful for curing a variety of diseases such as diabetes and CVD [6]. However, it cannot be expected to be without adverse effects as it is a completely aggressive surgery. Metabolic bone disease, development of gallstones, hyperoxaluria and deficiency of iron, vitamin B12, fat-soluble vitamins, thiamine, and folate are a number of common complaints that have been seen in the patients who went under this procedure [7-11].

Inflammation is a normal process in which the body responses to everyday diseases and injuries [12]. Therefore, it is considered an essential tool for the body to mend a destructed tissue and to recover after a disease. However, chronic inflammation suits the body for the potential diseases such as hay fever, atherosclerosis, rheumatoid arthritis, diabetes, and even cancer [13–18]. Recent studies have suggested a link between obesity and inflammation, as increased mass of adipose tissue may activate the immune process in white adipose tissue (WAT) and liver and immune cells [19]. WAT is the source of some pro-inflammatory cytokines such as tumor necrosis factor alpha (TNF- α) and interleukin-6 (IL-6), which both could be regarded as indicators of inflammation [20]. Interleukin 6 can also regulate C-reactive protein secretion which is an acute phase protein, and its serum level increases during inflammation; thus, it can also be a good marker of inflammation [21]. These three markers are considered the most important pro-inflammatory cytokines.

Previous studies exploring the impact of bariatric surgery on serum levels of IL-6, TNF- α , and CRP, as the most important biomarkers for inflammation, have reported inconclusive results. The controversy among the literatures might be due to differences in the obesity surgery, baseline weight, or follow-up period. Accordingly, the present systematic review and meta-analysis was performed to resolve these inconsistencies and to report pooled analysis for the effect of bariatric surgery on serum levels of IL-6, TNF- α , and CRP based on bassline body mass index, surgery type, and follow-up duration.

Methods

To perform this meta-analysis, the Preferred Reporting Items of Systematic Reviews and Meta-Analyses (PRISMA) statement guideline was used [22].

Search Strategy

A throughout search was conducted in PubMed/Medline and Scopus from inception to June 2018. The MeSH and non-MeSH terms were as follows: "bariatric surgery", "Roux-engastric bypass", "RYGB", "Laparoscopic Roux-en-gastric bypass", "LRYGB", "gastric bypass", "GB", "sleeve gastrectomy", "SG", "laparoscopic sleeve gastrectomy", "Billopancreatic Diversion", "BPD", "adjustable gastric banding", "AGB" "vertical banded gastroplasty", "VBG" AND "CRP", "C-Reactive Protein", "High Sensitive C-Reactive Protein", "hs-CRP", "Tumor Necrosis Factoralpha", "TNF- α ", "Interleukin-6", "IL-6". We hand searched all reference lists of eligible articles, related reviews, and meta-analyses as we did not want to miss any relevant studies. We did not include unpublished documents and gray literature like conference papers, theses, and patents.

Eligibility Criteria

Studies were included in this meta-analyses if they met the following criteria: (1) all were written in English; (2) were randomized or non-randomized trial studies; (3) only

executed on human, (4) reported baseline BMI and at least one of the following measures: CRP, IL-6, and TNF- α ; (5) performed one of the common bariatric surgery (RYGB, SG, VBG, AGB, BPD); (6) executed on patients with a BMI higher than 40 or 35 with at least one comorbidity (such as atherosclerosis, diabetes, and asthma). Articles were excluded if (1) the subjects had a BMI less than 35, (2) obesity was not the reason of surgery, and (3) had lack of sufficient data for the outcomes of interest in individuals. All editorials, reviews, letters to editors, conference papers, animal studies, and molecular studies were excluded. Totally in our initial search, we found 1163 papers. After removing duplicates, 1001 abstracts were selected for a more detailed review; subsequently, 863 studies were excluded due to following reasons: unrelated topic (667), inadequate information (177), non-English (3), animal studies (8), and review article (8). At last, 138 citations remained after screening for titles and abstracts. After full-text evaluation, 22 other studies were also excluded: (1) publication that evaluated the effect of bariatric surgery with combination of other treatments (n = 2), (2) papers which had the same database (n = 4) and, (3) studies that enough information was not stated in them (n = 16). After scrutinizing the full-text papers and based on our inclusion criteria, 114 prospective and 2 retrospective studies were chosen for the systematic review, and none of our included studies were excluded from the meta-analysis. PRISMA flow diagram of search process is depicted in Fig. 1.

Data Extraction

Two independent researchers (M. A., A. Sh.) did the study selection, whereas a chief investigator (Sh.A.) was also present to resolve any differences or controversies. In case of data deficiency, we contacted the corresponding author to acquire the necessary data. The following data were obtained from each study: first author's name; year of publication; study location; study duration; age and gender of participants; mean and SD of serum levels of CRP, IL-6, and TNF- α ; study design; health status of study population; number of participants in each groups; BMI before and after intervention; just if all individuals had the same disease, it was mentioned. If the mean inflammatory factors were not reported in the control group, it was considered a study without a control group.

Assessment of Study Quality

Two authors independently assessed the quality of the included studies by the Newcastle-Ottawa Quality Assessment Scale (NOS). This scale comprised three quality factors: selection (maximum 4 stars), comparability (maximum 2 stars), and outcome (maximum 3 stars). A maximum of 9 stars represents the highest quality. A total score of 7 or more was considered to indicate high-quality studies [23, 24].

Statistical Analysis

Mean difference was used as the effect size and a random effects model was utilized for the meta-analysis [25]. Using random-effects model, effect sizes were acquired as weighted mean difference (WMD) and 95% CI by the DerSimonian-Laird method. A test for heterogeneity was performed (using Q statistic and I^2) [26]. The subgroup analysis was conducted to find out possible sources of heterogeneity among included studies. A meta-regression analysis was performed to investigate whether participant baseline BMI and also duration of follow-up could explain heterogeneity across studies and also affect the measured effect size. Covariates for the meta-regression analysis were defined according to the results of the subgroup analysis and evidence-based knowledge. Publication bias was investigated by visual inspection of the funnel plot as well as by using the Egger's regression method. We used the sensitivity analysis to assess the effect of each study on the overall effect size by removing each study in turn. All statistical analyses were carried out using Stata MP V.14.0.

Results

Findings from Systematic Review

Characteristics of eligible studies are summarized in Table 1. The articles had been published between 2001 and 2017. The sample size of the included studies was between 5 and 765 participants (total sample size of studies (n = 8084). The control group was followed up only in four studies [27–30]. Across included studies, five were carried out in patient with diabetes [31–35], one study in patients with insulin resistance [36], one study in patients with asthma [37], two in metabolic syndrome [38, 39], one in atherosclerosis [40], and one in patients with Crohn's disease [41]. Twenty-two studies were just done on females [39, 42–62], one study on males [61], and the rest of the included studies were conducted on both genders [27–38, 40, 41, 63–142]. We considered all of the included studies for meta-analysis.

Study(disease)/year first author and year of study, *M* men, *W* women, *NI* initial sample size, *N2* final sample size, *FU* follow-up in months (M) and days (D), *Surgery* type of bariatric surgery performed, *Type* study design, *PNR* prospective non-randomized, *R* randomized, *Retro* retrospective, *BMI1* preoperative BMI, *BMI2* post-operative BMI, *AGE* defined as mean ± SD or (age interval), *Nr* not reported, *C* control group, *NO-scale* Newcastle Ottawa Scale, *RYGB* Roux-en-Y gastric bypass, *AGB* adjustable gastric banding, *SG* sleeve gastrectomy, *BPD* biliopancreatic diversion, Various combination of procedures, *VBG* vertical banded gastroplasty, *METs* metabolic syndrome, *insulin-R* insulin resistance, *PM* polymorphism, *gly* glycine, *ser* serine

Findings from Meta-Analysis

Bariatric Surgery and CRP

Among included studies which evaluated CRP as an outcome measure, BMI decreased significantly in patients following bariatric surgery (Supplemental Fig. 1). Overall, subgroup analysis (based on type of surgery) on the CRP changes after bariatric surgery was presented in Fig. 2. Combining 121 effect sizes revealed a significant decreasing effect of bariatric surgeries on the CRP levels of participants (WMD – 5.30, 95% CI – 5.46, – 5.15, P < 0.001). In addition, a between-study heterogeneity was found ($I^2 = 100\%$; $P_{heterogeneity} < 0.001$).

Furthermore, in subgroup analysis, a significant effect of various types of bariatric surgeries on the CRP levels except the BPD type was found. In addition, we found a decreasing effect of bariatric surgeries on the CRP levels of participants after different follow-up durations including less than 3 months, 6 months, 12 months, or more than 12 months follow-up duration; however, there was not any significant effect of bariatric surgeries on the CRP levels of participants after 3 months' follow-up duration. In addition, it has been shown significant increasing effect of bariatric surgeries on the CRP levels for studies which were conducted among individuals with a baseline BMI $< 40 \text{ kg/m}^2 \text{ or } > 50 \text{ kg/m2}$ (Table 2).

Bariatric Surgery and IL-6

Among included studies which investigated IL-6 as an outcome measure, BMI decreased significantly following bariatric surgery (Supplemental Fig. 2). Pooled effect size from random effect revealed that the IL-6 serum level decreased significantly following bariatric surgery (WMD – 0.58, 95% CI – 0.64, – 0.53), with significant heterogeneity among studies (I^2 97.7%, P < 0.001) (Fig. 3). Findings of subgroup analysis revealed a significant effect of different types of bariatric surgeries including RYGB, BPD, and other miscellaneous types on the IL-6 levels of individuals. According to these

Fig. 2 Overall subgroup analysis (based on type of surgery) on the CRP changes after bariatric surgery

analyses, we found a significant inverse influence of bariatric surgeries on IL-6 concentration for studies with 6 months and more duration of follow-up. In addition, a significant decreasing effect of bariatric surgeries on the IL-6 levels for studies which were conducted among individuals with a baseline BMI < 40 kg/m² or > 50 kg/m² was observed (Table 2).

Bariatric Surgery and TNF-a

Among included studies which studied the effect of bariatric surgery on TNF-a, BMI decreased significantly following bariatric surgery (Supplemental Fig. 3). The influence of bariatric surgeries on TNF- α concentration was indicated in Fig. 4. Thirty-nine effect sizes were pooled and an inverse influence in this regard was found (WMD - 0.20 95% CI -0.39, -0.02, P = 0.031), with significant heterogeneity among studies (l^2 95.4%, P < 0.001). Findings of subgroup analysis showed no significant effect of different types of bariatric surgeries on the TNF- α levels. We found a significant inverse influence of bariatric surgeries on TNF- α concentration for studies with 12 months' follow-up; however, there was not any significant increasing effect of bariatric surgeries on the TNF- α levels after other follow-up durations. In addition, a significant decreasing effect of bariatric surgeries on the TNF- α levels was found for studies which were conducted among individuals with a baseline BMI $< 40 \text{ kg/m}^2$ and ≥ 45 to > 50 kg/m² (Table 2).

Meta Regression Analysis

Meta-regression analysis indicated no linear relationship of baseline BMI with the absolute changes in CRP serum level, IL-6, and TNF- α . Moreover, no significant associations with follow-up duration and CRP, IL-6 and TNF- α were found, although a potential reducing trend of serum CRP was observed with follow-up duration and baseline BMI (Supplemental Fig. 4 and 5).

Publication Bias and Sensitivity Analysis

Sensitivity analysis was performed to assess the influence of each study on the pooled result (WMD) by removing each study in turn. Sensitivity analysis indicated that the result was not excessively influenced by any of the individual studies. There was no evidence of publication bias for studies investigating the effect of bariatric surgery on CRP (Egger's P = 0.29) and TNF- α (Egger's P = 0.21) based on Egger's test and by visual inspection of funnel plots (Supplemental Fig. 6); however, funnel plot and egger's linear test indicated significant publication bias among studies which evaluated the effect of bariatric surgery on IL-6 (P < 0.001) (Supplemental Fig. 6).

Discussion

Findings from our systematic review and meta-analysis indicate a significant reduction in the levels of various inflammatory cytokines including CRP, IL-6, and TNF- α as the most commonly measured inflammatory factors in bariatric surgery researches.

Obesity is associated with a moderate and chronic increase in such inflammatory factors which are hypothesized to decrease after bariatric surgeries [20, 21]. The results of this meta-analysis are in line with other studies looking at the effects of bariatric surgery on inflammatory factors. For instance, an earlier pooled analysis of cohort studies found a decreasing effect of bariatric surgeries on levels of CRP and IL-6 [143]. However, it must be noted that previous metaanalysis included only forty-eight studies. In the present study, 116 unique studies were included. A previous meta-analysis showed that only CRP and IL-6 decreased following bariatric surgery but TNF- α remained unchanged; in contrast, we showed that apart from CRP and IL-6, TNF- α also decreased significantly following bariatric surgery, which could be an important new finding in this field.

In the current study, we found significant effects of different bariatric surgeries on levels of CRP and IL-6 and TNF- α . These observed findings are in line with prior studies, which have illustrated an inverse effect of medical or dietary weight loss on obesity-induced inflammatory status. For instance, Heilbronn et al. observed that energy restriction and weight loss with very-low-fat diets reduce C-reactive protein concentrations among obese women [144]. Previous meta-analysis stated that the change in TNF- α after bariatric surgery was not significant. However, the correlation of TNF- α reduction and decrease in body mass index (BMI) varied among these studies. Bastard et al found that dietary methods of weight loss can reduce the levels of all three inflammatory markers including CRP, IL-6, and TNF- α [145], which is in line with our study. However, another randomized clinical trial has not indicated any significant attenuation of inflammation after neither medical nor dietary weight loss [88]. Also, data from a previous meta-analysis revealed a beneficial effect of low-fat diets [146] and exercise training on CRP levels regardless of the age or sex of the individuals [147]. Furthermore, animal and human studies have shown that bariatric surgeries might have a significant effect on both the adipose tissue inflammation and weight loss [148].

Although the biologic mechanisms by which bariatric surgery resolves inflammatory conditions are mostly unknown, weight loss followed by the surgery has been shown as one of the most important mechanisms that explain the reduction in levels of inflammatory factors [149]. Moreover, the correlation to other variables is inconsistent across bariatric surgery studies, including weight loss, blood pressure reduction, and change in lipids [150]. Probably, the major factor is the reduction of adipocyte mass through bariatric surgeries which is the Table 2 Subgroup analyses for the effect of bariatric surgery on CRP, IL-6, and TNF- α concentrations

mechanism responsible for the decline in inflammation state [149]. Thus, it would be expected that inflammatory markers would decrease linearly as BMI decreased. Perhaps, some other mechanism other than decreased BMI and fat mass, such as decreased caloric intake, decreased nutrient absorption, or decreased need for detoxification of ingested substances by the liver, may contribute to this reduction.

Inflammation is a highly significant risk factor for both morbidity and mortality. Inflammation is a highly significant risk factor for both morbidity and mortality [151]. It is wellidentified that long-term inflammation is associated with the increase risk of a vast number of chronic disease such as mood disorders [152], atherosclerosis, and coronary artery disease [153], neurodegenerative diseases [154], cancers [155], chronic obstructive pulmonary disease [156], hypertension [157], and diabetes [158]. Overall, our study showed a beneficial effect of bariatric surgery on inflammatory factors which may provide a protective effect against a number of metabolic health conditions of obesity, including diabetes, cardiovascular disease, and cancer as they all are associated with inflammation.

This meta-analysis has several strengths, such as this is the newest available data to show the effect of weight loss via various bariatric surgeries on the obesity-associated chronic inflammation. However, controversy between present study and previous meta-analysis could be due to fewer included studies in the previous meta-analysis, which can impact the pooled effect size.

In conclusion, findings from this meta-analysis of clinical trial studies suggested that bariatric surgeries might cause a significant reduction in the levels of various inflammatory markers including CRP, IL-6, and TNF- α .
